Language Assignment #1: Scheme

Issued: Tuesday, January 26 **Due:** Tuesday, February 9

Purpose

This assignment asks you to begin using a functional programming language named Scheme, which is a modern dialect of the venerable language Lisp. Lisp was designed by John McCarthy, at MIT, in 1958. Scheme was designed by Guy Steele and Gerald Sussman, at MIT, in 1975.

Submission

Homework is due at 11:59PM, Mountain Time, on the day it is due. Late work is not accepted. To submit your solution to an assignment, login to a lab computer, change to the directory containing the files you want to submit, and execute:

submit jbuffenb class assignment

For example:

submit jbuffenb cs101 hw1

The submit program has a nice man page.

Translator

In our lab, onyx is the home-directory file server for its nodes (e.g., onyxnode01). There is also a shared directory for "apps" mounted at /usr/local/apps. Nodes share a translator for Scheme, named guile, which is installed below /usr/local/apps, which is a non-standard location.

Due to shared-library constraints, onyx cannot execute guile. It can only be executed by a node.

Due to network constraints, onyx can be reached from the public Internet, but a node can only be reached from onyx. So, SSH and login to onyx, then SSH and login to a node.

An easy way to use guile, from a node, is to permanently add a line to the end of your .bashrc file. To do so, login to a random node, from onyx, by executing the script:

pub/bin/sshnode

Then, execute the script:

pub/bin/bashrc

Then, logout from the node and login to a node.

Documentation

Scheme lecture slides are at:

pub/slides/slides-scheme.pdf

Scheme is demonstrated by:

pub/sum/scheme

Scheme also is described in Section 11.3 of our textbook.

The interactive interpreter also has online documentation, for some functions. For example:

```
$ guile
...
Enter ',help' for help.
scheme@(guile-user)> ,d append
- Scheme Procedure: append . args
    Return a list consisting of the
    elements the lists passed as
    arguments.
...
scheme@(guile-user)>
```

Assignment

Write and fully demonstrate a Scheme function that implements a Tree Search And Replace operation. Your function should be named tsar, and have this interface:

```
(tsar subj srch repl)
```

A "tree" is simply a Scheme list (i.e., a symbolic expression, or s-expr). The function returns a *copy* of the list subj, with every sublist equal to srch replaced by a *copy* of repl. The function *returns* its result; it does not display anything. Any of the arguments might be a list or an atom.

For each replacement, instances of the atom 'RANDOM within repl replaced with a random number between 0 and 100, the result of: (random 100). This will demonstrate that proper copies are made. You might want to add this "feature" last.

For example:

```
(tsar 'z 'x 'y)

⇒ z
(tsar 'x 'x 'y)

⇒ y
(tsar 'x 'x 'x)

⇒ x
(tsar '() 'x 'y)

⇒ ()
(tsar '(x x) 'x 'y)
```

```
\begin{array}{l} \Rightarrow \ (y\ y) \\ (\text{tsar}\ '(x\ (x)\ z)\ 'x\ 'y) \\ \Rightarrow \ (y\ (y)\ z) \\ (\text{tsar}\ '(x\ (x)\ z)\ '(x)\ '(y\ y)) \\ \Rightarrow \ (x\ (y\ y)\ z) \\ (\text{tsar}\ '(x\ (x)\ ((x))\ z)\ '(x)\ '(y\ y)) \\ \Rightarrow \ (x\ (y\ y)\ ((y\ y))\ z) \\ (\text{tsar}\ '(x\ (x)\ ((x))\ z)\ '(x)\ '(y\ y)) \\ \Rightarrow \ (x\ (x)\ ((x))\ z)\ '(y\ y)\ y\ y\ z\ y\ y) \\ (\text{tsar}\ '(x\ (x)\ ((x))\ z)\ '(x)\ '(RANDOM\ y)) \\ \Rightarrow \ (x\ (74\ y)\ ((46\ y))\ z) \\ (\text{tsar}\ '(x\ (x)\ ((x))\ z)\ '(x)\ '(RANDOM\ RANDOM)) \\ \Rightarrow \ (x\ (76\ 76)\ ((63\ 63))\ z) \end{array}
```

Other Requirements

You are encouraged to define other functions, and call them from tsar.

The only builtin comparison function that you are allowed to use is eq?, for comparing atoms. Do not use the builtin function equal?, which is too much like a function I want you to write. Likewise, do not use the builtin function copy-tree.

You are required to use only a pure subset of Scheme:

- no side-effecting functions, with an exclamation mark in their names (e.g., set-car! and set-cdr!)
- no loops (e.g., do, foreach, and map)

Historically, students often want to use the builtin function append. There are several reasons why you should not use append:

- It doesn't really do what you want. Use cons.
- It is just a function. See:

```
pub/etc/append.scm
pub/etc/append1.scm
```

• It does not make a copy of its arguments, as required by parts of the assignment. Paraphrasing the reference manual: append doesn't modify the given arguments, but the return value may share structure with the final argument.

Test your solution thoroughly. The quality thoroughness of your tests will influence your grade.

Finally, do not try to find a solution on the Internet. You'll possibly be asked to solve a similar problem on an exam, and if you have not developed a solution on your own, you will not be able to do so on the exam.
